# Outline

- 1 Introduction
- 2 Brake orbit
- 3 Instability
- 4 Bifurcations

# Newtonian symmetric $N$ -body problem

- Configuration space (without collisions)

$$\mathcal{X} := \{q \in \mathbb{R}^{3N} \mid q_i \neq q_j, \forall i \neq j, q_1 + \dots + q_N = 0\}$$

- Newtonian gravitational potential

$$U(q) := \sum_{1 \leq i < j \leq N} \frac{Gm^2}{\|q_i - q_j\|}$$

- Set  $p := m(Id)\dot{q}$ , then

$$\dot{q}_i = \frac{\partial H}{\partial p_i}, \quad \dot{p}_i = -\frac{\partial H}{\partial q_i}, \quad i = 1, \dots, N$$

where  $H$  is the *Hamiltonian*:

$$H(q, p) = \sum_{i=1}^N \frac{\|p_i\|^2}{2m} - U(q).$$

# Symmetric Hamiltonian systems

Consider a smooth  $G$ -reversible equivariant (convex and superlinear) Hamiltonian ODE

$$\dot{x} = J\nabla H(x); \quad H : \mathbb{R}^{2n} \rightarrow \mathbb{R}, \quad J = \begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}.$$

Let  $x = (q, p)$ ,  $q$  = configuration,  $p$  = momentum and define

$$X_H(x) := J\nabla H(x).$$

There exists a representation  $\chi : G \rightarrow \{\pm 1\}$  such that

$$X_H(g.x) = \chi(g)g.X_H(x).$$

- $\Gamma = \ker \chi$  consists of spatial symmetries
- $G \setminus \Gamma$  are the time-reversing symmetries and

$$G/\Gamma \simeq \mathbb{Z}_2.$$

# Lagrangian formulation of Hamiltonian dynamics

$$\text{Lagrangian: } L(q, \dot{q}) = \sum_{i=1}^N \frac{\|\dot{q}_i\|^2}{2} + U(q).$$

Action functional

$$\mathcal{A}(c(t)) := \int_0^T L(c(t), \dot{c}(t)) dt.$$

with  $c(t) \in H^1([0, T], \mathcal{X})$  with boundary conditions

$$(c(0), c(T)) \in V \subset \mathbb{R}^n \times \mathbb{R}^n; \quad \text{e.g. } c(T) = Sc(0).$$

- 1  $\hat{c}(t)$  is a critical point of  $\mathcal{A}$  if  $\delta\mathcal{A}(\hat{c}(t))[h] = 0$ .
- 2 Critical points of  $\mathcal{A}$  are solution trajectories of  $\dot{x} = X_H(x)$ ;

$$H(q, p) = p^T \dot{q} - L(q, \dot{q}).$$

## 4-body problem: the Hip-Hop orbit

- Configuration space:  $\mathcal{X} \simeq \mathbb{R}^{12}$ .
- **Thm** (Chenciner-Venturelli (1999)): There exists a collisionless  $4T$ -periodic orbit  $\widehat{c}(t)$  minimizing

$$\mathcal{A}_{[-T, T]}(c(t)) = \int_{-T}^T L(c(t), \dot{c}(t)) dt,$$

given  $\Lambda = \{c \in H^1([-T, T], \mathcal{X}) \mid c(t - T) = -c(t + T)\}$ .

# The Hip-Hop orbit

The Hip-Hop orbit is obtained as a special realization of the above minimizer as follows.

- Let  $A(x, y, z) = (-y, x, -z)$  and

$$\rho \cdot (q_1, q_2, \dots, q_{2n}) = (Aq_{2n}, Aq_1, \dots, Aq_{2n-1})$$

- $\mathbb{Z}_{2n} := \langle (A, \rho) \rangle$  and set  $\mathcal{C} := \text{Fix}(\mathbb{Z}_{2n})$ .
- Lift symplectically  $(A, \rho)$  to  $T^*\mathcal{X}$ .

# Reduced Hip-Hop orbit

**Thm** (CV (1999), Terracini-Venturelli (2007)): There exists a collisionless  $4T$ -periodic orbit  $\widehat{q}(t)$  minimizing

$$\min \mathcal{A}(q(t)), \quad \text{over}$$

$$\Lambda_{\mathbb{Z}_{2n}} = \{q \in H^1(\mathbb{R}/4T\mathbb{Z}, \mathcal{C}) \mid q(t - T) = q(t + T)\}.$$

The orbit  $\widehat{q}(t)$  is not a relative equilibrium, has nonzero angular momentum  $\mu$  and is not planar.

- 1 On  $\mathcal{C}$ , the dynamics of all bodies follows the first one.
- 2  $X_H$  restricted to  $T^*\mathcal{C}$  is a 3-degrees of freedom system.
- 3 **Conjecture:** It is a brake orbit.

# Symmetry and Reduction

- $X_H(q, p)$  has reversing-symmetry  $G = \mathbf{O}(3) \times \mathbf{S}_{2n} \times \mathbb{Z}_2(\mathbf{S}_2)$ .
- $W(\mathbb{Z}_{2n}) \simeq (\mathbf{SO}(2) \times \mathbb{Z}_2) \times \mathbb{Z}_2(k) \times \mathbb{Z}_2(\mathbf{S}_2)$  acts on  $T^*\mathcal{C}$ .
- Momentum map:  $J : T^*\mathcal{C} \rightarrow T_1^*\mathbf{SO}(2)$
- $J^{-1}(\mu)/\mathbf{SO}(2)$  is 4-D with amended potential:  $U_\mu(x)$
- $\mathbb{D}_2(\mathbf{S}_1, \mathbf{S}_2)$  acts on  $J^{-1}(\mu)/\mathbf{SO}(2)$  where
 
$$\mathbf{S}_1 = \text{diag}(\sigma, -\sigma) \quad \sigma = \text{diag}(1, -1) \quad \text{and} \quad \mathbf{S}_2 = \text{diag}(I, -I).$$

$$\mathcal{X} \rightarrow \mathcal{X}/\mathbf{SO}(2)$$

$$(r(t), \theta(t), d(t)) \mapsto (r(t), d(t)).$$

### Numerical algorithm:

- Truncated Fourier series for  $q_i(t)$ ,  $i = 1, 2, 3, 4$ .
- Minimisation of a function (discretized integral) depending on Fourier coefficients  $\alpha, \beta$ :

$$\mathcal{G}(\alpha, \beta) := \sum_{j=1}^k L(q^f(t_j, \alpha, \beta), \dot{q}^f(t_j, \alpha, \beta)).$$

## Brake orbit

Consider  $H^{-1}(h)$ , the Hill's region is

$$N_h = \{x \in \mathcal{S}/\mathbf{S}^1 \mid U_\mu(x) \leq h\}.$$

A *brake orbit* is an orbit of  $X_H|_{H^{-1}(h)}$  which projects to a trajectory of  $\mathcal{X}$  in  $N_h$  which intersects  $\partial N_h$  in two distinct points only.

**Theorem (Lewis *et al.* online DCDS-A (2013))**

*If  $\hat{q}(t)$ ,  $-T \leq t \leq T$ , minimizes the action  $\mathcal{A}_{[-T, T]}$  on the function space  $H^1([-T, T], \mathcal{C})$ , then the corresponding loop  $x(t)$  in reduced configuration space with  $-2T \leq t \leq 2T$ , is a brake orbit in the Hill's region*

# Idea of the proof

Figure: Symmetric across the horizontal  $r$ -axis

FIGURE 2. An anti-symmetric loop in  $TC$  whose projection in  $T(\mathcal{C}/S^1)$  has a transverse self-intersection (inset).  
Stability Analysis and Bifurcations of the Hip-Hop orbit

FIGURE 3. The non-smooth curves  $q_1$  and  $q_2$  constructed from the loop of Figure 2, and their projections in  $T(\mathcal{C}/S^1)$  (inset).

# Symplectic matrices

Consider the linearisation of  $X_H$  near  $x(t)$ :

$$\dot{\xi} = dX_H(x(t))\xi, \quad \xi(0) = Id \quad (1)$$

and let  $\gamma(t)$  be the fundamental matrix solution of (1).

- $\gamma(t)$  is symplectic for all  $t \in \mathbb{R}$ .
- Eigenvalues of symplectic matrices come in quadruplets:  $\{\lambda, \lambda^{-1}, \bar{\lambda}, \bar{\lambda}^{-1}\}$ .

unstable

linearly stable  
(elliptic)

# Lagrangian subspaces

- Consider,  $(\mathbb{R}^{2n}, \omega)$  a symplectic space with  $\omega(u, v) := u^* J v$
- A subspace  $W \subset V$  is *Lagrangian*

$$\omega|_{W^2} = 0 \quad \text{and} \quad \dim W = n.$$

- Lagrangian Grassmanian  $\Lambda(n)$ : manifold of all Lagrangian subspaces in  $\mathbb{R}^{2n}$ .
- A symplectic matrix,  $W$  Lagrangian subspace  
 $\Rightarrow AW$  Lagrangian subspace.

# Maslov index and focal points

- Let  $\gamma : [a, b] \rightarrow \Lambda(n)$  be a continuous path.
- Maslov index: for  $0 < \epsilon \ll 1$

$$\mu(\alpha, \gamma(t)) := [e^{-\epsilon J} \gamma(t), \overline{\Lambda^1(\alpha)}].$$

- Let  $W$  be a Lagrangian subspace, a point  $\tau \in (a, b)$  is a *focal point* if

$$d\phi_\tau W \cap \text{Ver} \neq \{0\}, \quad \text{where} \quad \text{Ver} = \{(0, v)^* \mid v \in \mathbb{R}^n\}.$$

$\text{Ver}$  is a Lagrangian subspace.

- If  $\alpha = \text{Ver} := \{(0, v)^* \mid v \in \mathbb{R}^n\}$ ,

$$\mu(d\phi_t W, \alpha) = \# \text{ focal points.}$$

# General Idea

- Offin (1994,2000), Offin and Cabral (2009), B and Offin.

- 1 Choice of  $W$  is crucial.
- 2  $d\phi_t W \cap V = \{0\}$ ,  $t \in [0, T/m]$ : Tool - Comp. Thm (Arnol'd 1985)
- 3 Comp Thm (Offin 2000) +  $\delta^2 \mathcal{A}(\hat{c}(t)) \geq 0$ :

$$d\phi_t W \cap V = \{0\} \implies d\phi_t(Sd\phi_{T/m} W) \cap V = \{0\} \text{ on } [0, T/m]$$

# Result of Hu and Sun does not apply

## Theorems (Hu and Sun (2009))

- ① For a critical point  $\widehat{c}(t)$  of a variational problem with BC  $\overline{S}c(t) = c(t + T/m)$

$$\text{Morse index}(\widehat{c}(t)) + \ker(\overline{S} - I) = \mu(\text{Gr}(S^T), \text{Gr}(\gamma(t)))$$

- ② Let  $z(t)$  be a periodic solution with spatio-temporal symmetry  $Sz(t) = z(t + T/m)$ ,  $S = \text{diag}(\overline{S}, \overline{S})$ . If

$$\mu(\text{Gr}(S), \text{Gr}(\gamma(t)))$$

is **odd** then  $z(t)$  is unstable.

**Hip-Hop orbit:** Morse index = 0,  $\overline{S} = -I \Rightarrow \mu(\text{Gr}(S), \text{Gr}(\gamma(t))) = 0$ .

# Instability Theorem

Theorem (Lewis *et al.* online DCDS-A (2013))

*The reduced hip hop orbit  $z(t)$  is **hyperbolic** in the energy surface  $H^{-1}(h)$  when it is dynamically non-degenerate. If the unreduced variational problem is non-degenerate then the reduced hip hop orbit is **(linearly) unstable**.*

## Focal points of Hip-Hop orbit

- 1 Choice of Lag. subspace:  $W = X_H(z(0)) \oplus u$ , where  $u \in \text{Fix}(S_1)$ .  $W \in TH^{-1}(h)$ .
- 2 The only focal points of  $W$  on  $[-T, T]$  are the brake point
 
$$X_H(-T) = X_H(T).$$
- 3  $Y = T_{z(t)}H^{-1}(h)/X_H(z)$  is a symplectic space and  $W'$  projection of  $W$  to  $Y$  is a  $1D$  Lagrangian subspace of  $Y$  with no focal points on  $[0, 2T]$ .
- 4 Consecutive  $(Sd\phi_{2T})^n W'$  are transverse and have no focal points in  $[0, 2T]$

$$\Rightarrow d\phi_t W' \cap V = \{0\} \quad 0 \leq t < \infty.$$

# Numerical Poincaré map

Poincare map at  $h = -1.9211$

# Bifurcations of the Hip-Hop orbit: Buono *et al.* (in prep)

$P : Y \rightarrow Y$  Application de Poincaré

$Q : Y \rightarrow Y$

$Q(x) = S f_{t(x)}(x)$

$P = Q^2$

- $Y$  is a  $S_2$ -invariant Poincaré section.
- $(dP) = (dQ)^2$  implies suppression of period doubling.
- $Q$  is  $S_2$ -reversible:  $Q \circ S_2 = S_2 \circ Q^{-1}$

$$dQ(0) = \begin{pmatrix} a & b \\ c & a \end{pmatrix}, \quad \begin{pmatrix} \pm 1 & b \\ 0 & \pm 1 \end{pmatrix} \text{ or } \begin{pmatrix} \pm 1 & 0 \\ c & \pm 1 \end{pmatrix}.$$

- 1 Classification of symmetry-breaking bifurcations of periodic orbits with  $\mathbb{D}_2$ -reversing symmetry group (Lamb et al (2003)):

Rev	$L_0$	$K$	$\Delta^{bif}$	$\Sigma^{bif}$	$\sigma^{bif}$	$\rho^{bif}$
Y	+1	$\mathbb{D}_2(S_2, L_0)$	1	$\mathbb{D}_2(S_2, S)$	$S$	$S_2$
N	+1	$\mathbb{Z}_2(L_0)$	1	$\mathbb{Z}_2(S)$	$S$	1
Y	-1	$\mathbb{Z}_2(S_2)$	1	$\mathbb{Z}_2(S_2)$	1	$S_2$
Y	-1	$\mathbb{Z}_2(S_2 L_0)$	1	$\mathbb{Z}_2(S_1)$	1	$S_1$

- 2 Bifurcation diagrams: +1 eigenvalue (left), -1 eigenvalue (right).

Case A

Case B
