# Six-vertex and Ashkin-Teller models: order/disorder phase transition 

Alexander Glazman<br>University of Fribourg

19th November 2019

- Dimers, Ising model and their interactions -

joint work with:<br>Ron Peled

## Structure of the talk

FK model ${ }^{\circ}$

FK model with
boundary-cluster weight $q_{b}$

## Part 1: Ashkin-Teller model

FK model ${ }^{\circ}$

FK model with
boundary-cluster weight $q_{b}$

## Ashkin-Teller model: definition

Finite domain $\Omega \subset \mathbb{Z}^{2}($ box $N \times N)$.
A pair of spin configurations: $\tau, \tau^{\prime} \in\{+1,-1\}^{V(\Omega)}$.
Boundary conditions (free, + ): $\tau=\tau^{\prime}$ on $\partial \Omega$.
'43 Ashkin-Teller model with parameters $J, U \in \mathbb{R}$ :

$$
\mathrm{AT}_{\Omega, J, U}^{\mathrm{free},+}=\frac{1}{Z} \cdot \exp \left[\sum_{i \sim j} J\left(\tau_{i} \tau_{j}+\tau_{i}^{\prime} \tau_{j}^{\prime}\right)+U \tau_{i} \tau_{i}^{\prime} \tau_{j} \tau_{j}^{\prime}\right] .
$$

Case $U=0$ : two independent Ising models.
Question: ordering in $\tau, \tau^{\prime}, \tau \tau^{\prime}$ ?

## Ashkin-Teller model: conjectured phase diagram

## Ashkin-Teller model: conjectured phase diagram

## Ashkin-Teller model: conjectured phase diagram

 $\exp \left[\sum_{i \sim j} J\left(\tau_{i} \tau_{j}+\tau_{i}^{\prime} \tau_{j}^{\prime}\right)+U \tau_{i} \tau_{i}^{\prime} \tau_{j} \tau_{j}^{\prime}\right]$ Known results:

- three distinct regimes when U/J >> 1 [Pfister '82]
- $J>U$ : sharp phase transition at the self-dual curve
[Duminil-Copin-Raoufi-Tassion '18]

## Theorem

Let $J<U$ be such that $\sinh 2 J=e^{-2 U}$. Then the weak limit $\mathrm{AT}_{J, U}^{\text {free,+ }}$ under (free, + ) b.c. exists and exhibits exponential decay of correlations of $\tau$ (and $\tau^{\prime}$ ) and ordering of the product $\tau \tau^{\prime}$ :

$$
\mathrm{AT}_{J, U}^{\text {free, }+}\left(\tau_{i} \tau_{j}\right) \leq C e^{-\alpha|i-j|} \quad \operatorname{AT}_{J, U}^{\text {free, }+}\left(\tau_{i} \tau_{i}^{\prime} \tau_{j} \tau_{j}^{\prime}\right) \geq \delta,
$$

for some $C, \alpha, \delta>0$ depending on $J, U$.

## Ashkin-Teller $\leftrightarrow$ Six-vertex: coupling via duality

$$
\mathrm{AT}_{\Omega, J, U}^{\text {free },+} \propto \exp \left[\sum_{i \sim j} J\left(\tau_{i} \tau_{j}+\tau_{i}^{\prime} \tau_{j}^{\prime}\right)+U \tau_{i} \tau_{i}^{\prime} \tau_{j} \tau_{j}^{\prime}\right]
$$

## Ashkin-Teller $\leftrightarrow$ Six-vertex: coupling via duality

## Ashkin-Teller $\leftrightarrow$ Six-vertex: coupling via duality

$\mathrm{AT}_{\Omega, J, U}^{\text {free, }+} \propto \exp \left[\sum_{i \sim j} J\left(\tau_{i} \tau_{j}+\tau_{i}^{\prime} \tau_{j}^{\prime}\right)+U_{\tau_{i}} \tau_{i}^{\prime} \tau_{j} \tau_{j}^{\prime}\right]$ FK-Ising-type representation $\xi^{*}$ :

- if $\tau_{i}=\tau_{j}$ and $\tau_{i}^{\prime}=\tau_{j}^{\prime}$, then $i j \in \xi^{*}$ w.p. $1-e^{-4 J}$ and $i j \notin \xi^{*}$ w.p. $e^{-4 J}$

## Theorem

- Order when $c>2$ : convergence of measures with $0 / 1$ b.c., all extremal transl.-inv. Gibbs measures can be obtained as limits under $n / n+1$ b.c., for some $n$; $\xi$ has an infinite cluster with logarithmically small holes.
- Disorder when $c=2$ : logarithmic variations of heights, no extremal transl.-inv. Gibbs measures; spin measures under + and - b.c. are the same.
- FKG: marginals $\sigma^{\bullet}$ and $\sigma^{\circ}$ when $c \geq 1$; marginal on $\xi$ when $c \geq 2$.

When $c=2, \xi$ coincides with the critical FK configuration at $q=4$.

## Six-vertex $\leftrightarrow$ random-cluster: Baxter-Kelland-Wu coupling

$h \sim$ height function on $\mathcal{D}$ with $0 / 1$ b.c. and parameter $c=e^{\lambda / 2}+e^{-\lambda / 2} \geq 2$
$\eta \sim$ critical FK config. on $\mathcal{D}^{\bullet}$ with free b.c. and parameter $q=\left[e^{\lambda}+e^{-\lambda}\right]^{2} \geq 4$

## Proposition

Variables $h$ and $\eta$ can be coupled in such a way that $h$ is constant on clusters of $\eta$ and $\eta^{*}$. The joint law can be written in either of the two following ways:

$$
\begin{align*}
& (h, \eta) \sim \exp \left[\lambda \sum_{\mathcal{C} \sim \mathcal{C}^{*} \text { clusters }}\left(h\left(\mathcal{C}^{*}\right)-h(\mathcal{C})\right)(-1)^{\mathbb{1}_{\mathcal{C} \text { inside }} \mathcal{C}^{*}}\right],  \tag{1}\\
& (h, \eta) \sim \exp \left[\frac{\lambda}{4} \sum_{i \sim j \text { black }}\left(h(i)+h(j)-h\left(i^{*}\right)-h\left(j^{*}\right)\right)(-1)^{\mathbb{1}_{i j \text { open }}}\right] . \tag{2}
\end{align*}
$$

$q=\left[e^{\lambda}+e^{-\lambda}\right]^{2} \geq 4$. Coupling $-h$ is constant on clusters of $\eta$ and $\eta^{*}$,

$$
\begin{equation*}
(h, \eta) \sim \exp \left[\lambda \sum_{\mathcal{C} \sim \mathcal{C}^{*} \text { clusters }}\left(h\left(\mathcal{C}^{*}\right)-h(\mathcal{C})\right)(-1)^{\mathbb{1}_{\mathcal{C} \text { inside } \mathcal{C}^{*}}}\right] \tag{1}
\end{equation*}
$$

(1): clusters of $\eta$ or $\eta^{*}$ contribute $e^{\lambda}+e^{-\lambda}$; use $k\left(\eta^{*}\right)-k(\eta) \sim|\eta|, \frac{p_{c}}{1-p_{c}}=\sqrt{q}$ :

$$
\begin{aligned}
\sum_{h \perp \eta, \eta^{*}}(1) \propto \sqrt{q}^{k(\eta)+k\left(\eta^{*}\right)} & =\sqrt{q}^{k\left(\eta^{*}\right)-k(\eta)} \sqrt{q}^{2 k(\eta)} \propto\left(\frac{p_{c}}{1-p_{c}}\right)^{\# \operatorname{open}(\eta)} q^{k(\eta)} \\
& \propto p_{c}^{\# \operatorname{open}(\eta)}\left(1-p_{c}\right)^{\# \operatorname{closed}(\eta)} q^{\# \operatorname{clusters}(\eta)}
\end{aligned}
$$

$c=e^{\lambda / 2}+e^{-\lambda / 2} \geq 2$. Coupling $-h$ is constant on clusters of $\eta$ and $\eta^{*}$,

$$
\begin{gather*}
(h, \eta) \sim \exp \left[\frac{\lambda}{4} \sum_{i \sim j \text { black }}\left(h(i)+h(j)-h\left(i^{*}\right)-h\left(j^{*}\right)\right)(-1)^{\mathbb{1}_{i j} \text { open }}\right]  \tag{2}\\
\text { (1) 0 } \\
0
\end{gather*}
$$

(2): ij contributes $e^{\lambda / 2}+e^{-\lambda / 2}$ if $h(i)=h(j)$ and $h\left(i^{*}\right)=h\left(j^{*}\right)$ and 1 , otherwise.

## Six-vertex $\leftrightarrow$ random-cluster: boundary weights

$h \sim$ height function on $\mathcal{D}$ with $0 / 1$ b.c. and parameter $c=e^{\lambda / 2}+e^{-\lambda / 2} \geq 2$ $\eta \sim$ critical FK config. on $\mathcal{D}^{\bullet}$ with free b.c. and parameter $q=\left[e^{\lambda}+e^{-\lambda}\right]^{2} \geq 4$

## Part 4: FK model with boundary-cluster weight $c_{b}$

## FK model with weight $q_{b} \in[1, q]$ for boundary clusters

Parameters $p \in(0,1), q, q_{b}>0$, finite $G \subset \mathbb{Z}^{2}, \omega \in\{\text { open, closed }\}^{E(G)}$ :

$$
\begin{gathered}
\operatorname{FK}_{G, q, p}^{q_{b}}(\omega)=p^{\# \operatorname{open}(\omega)}(1-p)^{\# \operatorname{closed}(\omega)} q^{\# \operatorname{bulk-clusters}(\omega)} q_{b}^{\# \partial-\operatorname{clusters}(\omega)} \\
\begin{array}{cc}
\text { wired } & \text { free }
\end{array}
\end{gathered}
$$

Fix $q \geq 1$. Measures $\mathrm{FK}_{G, q, p}^{q_{b}}$ are stochastically ordered when $q_{b} \in[1, q]$, interpolating between wired $\left(q_{b}=1\right)$ and free $\left(q_{b}=q\right)$ b.c.

## FK model with weight $q_{b} \in[1, q]$ for boundary clusters

Parameters $p \in(0,1), q, q_{b}>0$, finite $G \subset \mathbb{Z}^{2}, \omega \in\{\text { open, closed }\}^{E(G)}$ :

$$
\begin{gathered}
\operatorname{FK}_{G, q, p}^{q_{b}}(\omega)=p^{\# \operatorname{open}(\omega)}(1-p)^{\# \operatorname{closed}(\omega)} q^{\# \operatorname{bulk} \text {-clusters }(\omega)} q_{b}^{\# \text {-clusters }(\omega)} \\
\xrightarrow[\text { wired }]{\stackrel{\text { wree }}{ }} \xrightarrow[\text { fre }]{ }
\end{gathered}
$$

Fix $q \geq 1$. Measures $\mathrm{FK}_{G, q, p}^{q_{b}}$ are stochastically ordered when $q_{b} \in[1, q]$, interpolating between wired $\left(q_{b}=1\right)$ and free $\left(q_{b}=q\right)$ b.c.

- If $p \neq p_{c}$, then the infinite-volume limit does not depend on $q_{b}$.
- Same at $p=p_{c}$ when $q \in[1,4]$.
- Measure dual to $\mathrm{FK}_{G, q, p_{c}}^{q_{b}}$ is $\mathrm{FK}_{G^{*}, q, p_{c}}^{q^{*}}$ with $q_{b}^{*}=q / q_{b}$.

## FK model with weight $q_{b} \in[1, q]$ for boundary clusters

Parameters $p \in(0,1), q, q_{b}>0$, finite $G \subset \mathbb{Z}^{2}, \omega \in\{\text { open, closed }\}^{E(G)}$ :

Fix $q \geq 1$. Measures $\mathrm{FK}_{G, q, p}^{q_{b}}$ are stochastically ordered when $q_{b} \in[1, q]$, interpolating between wired $\left(q_{b}=1\right)$ and free $\left(q_{b}=q\right)$ b.c.

- If $p \neq p_{c}$, then the infinite-volume limit does not depend on $q_{b}$.
- Same at $p=p_{c}$ when $q \in[1,4]$.
- Measure dual to $\mathrm{FK}_{G, q, p_{c}}^{q_{b}}$ is $\mathrm{FK}_{G^{*}, q, p_{c}}^{q^{*}}$ with $q_{b}^{*}=q / q_{b}$.

## Theorem

Take $q=\left[e^{\lambda}+e^{-\lambda}\right]^{2}, \lambda>0$. Then $\mathrm{FK}_{q, p_{c}}^{q_{b}}=\mathrm{FK}_{q, p_{c}}^{\text {wired }}$ if $q_{b} \in\left[1, e^{-\lambda} \sqrt{q}\right]$ and $\mathrm{FK}_{q, p_{c}}^{q_{b}}=\mathrm{FK}_{q, p_{c}}^{\mathrm{free}}$ if $q_{b} \in\left[e^{\lambda} \sqrt{q}, q\right]$.

Conjecture: Phase transition at $q_{b}=\sqrt{q}$.

## Part 5: proofs

FK model ${ }^{\circ}$

FK model with
boundary-cluster weight $q_{b}$

## Proof, step 1: building on the FK model

- Russo-Seymour-Welsh theory at $p_{c}$ when $q=4$ implies logarithmic fluctuations of the height function at $c=2$
- If $q>4, p=p_{c}$, wired b.c. $\Rightarrow$ infinite cluster with log. small holes $\Rightarrow$
- uniformly bdd fluctuations of height functions when $c=e^{\lambda / 2}+e^{-\lambda / 2}, \lambda>0$
- under 0,1 b.c. if $\mathcal{D}_{k}$ is a sequence of even domains, then height-function measures with $c_{b}=e^{\lambda / 2}$ converge, the limit $\mathrm{HF}_{c, \text { even }}^{0,1 ; e^{\lambda / 2}}$ is extremal, transl. inv., has an infinite cluster of height 0 , with logarithmically small holes
- $\mathrm{HF}_{c, \text { odd }}^{0,1 ; e^{\lambda / 2}}$ is defined similarly, infinite cluster of height 1

Proof, step 2: $\mathrm{HF}_{c, \text { even }}^{0,1, \mathrm{e}^{\mathrm{e}} / 2} \preceq \mathrm{HF}_{c, 0 \text { odd }}^{0,1, i^{\mathrm{e}} / 2}$ $c=e^{\lambda / 2}+e^{-\lambda / 2}$. Let $\mathcal{D}$ be an even domain.

## 

$c=e^{\lambda / 2}+e^{-\lambda / 2}$. Let $\mathcal{D}$ be an even domain.
Positive association of heights $\Rightarrow$ imposing height 1 on $\partial \mathcal{D}$ increases the measure:

$$
\mathrm{HF}_{c, \mathcal{D}}^{0,1 ; e^{\lambda / 2}} \preceq \mathrm{HF}_{c, \mathcal{D} \backslash \partial \mathcal{D}}^{0,1 ; c}
$$

## Proof, step 2: $\mathrm{HF}^{0,1 ; i^{e} / 2} \prec \mathrm{HF}^{0,1 ; i^{e} / 2}$

$c=e^{\lambda / 2}+e^{-\lambda / 2}$. Let $\mathcal{D}$ be an even domain.
Positive association of heights $\Rightarrow$ imposing height 1 on $\partial \mathcal{D}$ increases the measure:

$$
\mathrm{HF}_{c, \mathcal{D}}^{0,1 ; \mathrm{e}^{\lambda / 2}} \preceq \mathrm{HF}_{c, \mathcal{D} \backslash \partial \mathcal{D}}^{0,1 ; c}
$$

Domain $\mathcal{D} \backslash \partial \mathcal{D}$ is odd. Monotonicity in the boundary parameter $c_{b}$ :

$$
\mathrm{HF}_{c, \mathcal{D} \backslash \partial \mathcal{D}}^{0,1 ; c} \preceq \mathrm{HF}_{c, \mathcal{D} \backslash \partial \mathcal{D}}^{0,1 ; e^{\lambda / 2}}
$$

## Proof, step 2: $\mathrm{HF}_{\text {ceven }}^{0,1 ; \mathrm{e}^{\mathrm{e}} / 2} \prec \mathrm{HF}^{0,1 ; i^{e} / 2}$

$c=e^{\lambda / 2}+e^{-\lambda / 2}$. Let $\mathcal{D}$ be an even domain.
Positive association of heights $\Rightarrow$ imposing height 1 on $\partial \mathcal{D}$ increases the measure:

$$
\mathrm{HF}_{c, \text { even }}^{0,1 ; \mathrm{e}^{\lambda / 2}} \leftarrow \mathrm{HF}_{c, \mathcal{D}}^{0,1 ; \mathrm{e}^{\lambda / 2}} \preceq \mathrm{HF}_{c, \mathcal{D} \backslash \partial \mathcal{D}}^{0,1 ; c}
$$

Domain $\mathcal{D} \backslash \partial \mathcal{D}$ is odd. Monotonicity in the boundary parameter $c_{b}$ :

$$
\mathrm{HF}_{c, \mathcal{D} \backslash \partial \mathcal{D}}^{0,1 ; c} \preceq \mathrm{HF}_{c, \mathcal{D} \backslash \partial \mathcal{D}}^{0,1 ; e^{\lambda / 2}} \rightarrow \mathrm{HF}_{c, o d d}^{0,1 ; e^{\lambda / 2}}
$$

## Proof, step 3.1: $\mathrm{HF}^{0,1 ; \mathrm{e}^{\lambda / 2}} \succ \mathrm{HF}^{0,1 ; \mathrm{e}^{\lambda / 2}}$

Consider $\mathbb{T}^{\circ}$ : each odd site $(i, j)$ is linked to $(i, j \pm 1)$, $(i \pm 1, j),(i \pm 2, j)$. This is a triangular lattice. By duality and extremality, one of the following holds:

$$
\begin{align*}
& \left.\mathrm{HF}_{c, \text { even }}^{0,1 ; e^{\lambda / 2}} \text { (around every box, exists a } \mathbb{T}^{\circ} \text {-circuit of height } \geq 1\right)=1  \tag{3}\\
& \left.\mathrm{HF}_{c, \text { even }}^{0,1 ; e^{\lambda / 2}} \text { (exists an infinite } \mathbb{T}^{\circ} \text {-cluster of height } \leq-1\right)=1 \tag{4}
\end{align*}
$$

## Proof, step 3.1: $\mathrm{HF}_{c, 1, \mathrm{e}^{\lambda / 2}}^{0, \mathrm{HF}_{c}^{0,1 ; \mathrm{e}^{\lambda / 2}}}$

Consider $\mathbb{T}^{\circ}$ : each odd site $(i, j)$ is linked to $(i, j \pm 1),(i \pm 1, j),(i \pm 2, j)$. This is a triangular lattice. By duality and extremality, one of the following holds:

$$
\begin{align*}
& \left.H F_{c, \text { even }}^{0,1 ; e^{\lambda / 2}} \text { (around every box, exists a } \mathbb{T}^{\circ} \text {-circuit of height } \geq 1\right)=1  \tag{3}\\
& \left.H F_{c, \text { even }}^{0,1 ; e^{\lambda / 2}} \text { (exists an infinite } \mathbb{T}^{\circ} \text {-cluster of height } \leq-1\right)=1 \tag{4}
\end{align*}
$$

If (4) occurs, then the same holds for heights $\geq 1$ (FKG for the heights). Such coexistence is excluded [Sheffiled '05], [Duminil-Copin-Raoufi-Tassion '18]

## Proof, step 3.1: $\mathrm{HF}_{c, \text { even }}^{0,1 e^{\lambda / 2}} \succeq \mathrm{HF}_{c, 1 \mathrm{e}^{1 / 2}}^{0,1 \mathrm{e}^{\lambda / 2}}$

Consider $\mathbb{T}^{\circ}$ : each odd site $(i, j)$ is linked to $(i, j \pm 1)$, $(i \pm 1, j),(i \pm 2, j)$. This is a triangular lattice. By duality and extremality, one of the following holds:

$$
\begin{align*}
& \left.\mathrm{HF}_{c, \text { even }}^{0,1 ; e^{\lambda / 2}} \text { around every box, exists a } \mathbb{T}^{\circ} \text {-circuit of height } \geq 1\right)=1  \tag{3}\\
& \left.\mathrm{HF}_{c, \text { even }}^{0,1 ; e^{\lambda / 2}} \text { (exists an infinite } \mathbb{T}^{\circ} \text {-cluster of height } \leq-1\right)=1 \tag{4}
\end{align*}
$$

If (4) occurs, then the same holds for heights $\geq 1$ (FKG for the heights). Such coexistence is excluded [Sheffiled '05], [Duminil-Copin-Raoufi-Tassion '18] Hence (3) occurs. Modifying locally, obtain $\mathbb{T}^{\circ}$-circuits of height 1.

## Proof, step 3.2: $\mathrm{HF}_{c, \text { even }}^{0,1 ; \mathrm{e}^{\lambda / 2}} \succeq \mathrm{HF}_{c, 0 \mathrm{odd}}^{0,1 ; \mathrm{e}^{\lambda / 2}}$

Similarly, for $H F_{c, \text { odd }}^{0,1 ; e^{\lambda / 2}}$ and $\mathbb{T}^{\bullet}$-circuits of height 0 . We get:
$\mathrm{HF}_{c, \text { even }}^{0,1 ; \mathrm{e}^{\lambda / 2}}\left(\right.$ around every box, exists a $\mathbb{T}^{\circ}$-circuit of height 1 ) $=1$
$\mathrm{HF}_{c, \text { odd }}^{0,1 ; \mathrm{e}^{\lambda / 2}}\left(\right.$ around every box, exists a $\mathbb{T}^{\bullet}$-circuit of height 0$)=1$
Couple $f \sim \mathrm{HF}_{c, \text { even }}^{0,1 ; \mathrm{e}^{\lambda / 2}}$ and $g \sim \mathrm{HF}_{c, \text { odd }}^{0,1 ; \mathrm{e}^{\lambda / 2}}$ in the following way:

## Proof, step 3.2: $\mathrm{HF}_{c, \text { even }}^{0,1 \mathrm{e}^{\lambda / 2}} \succeq \mathrm{HF}_{c, \text { odd }}^{0,1, \mathrm{e}^{\lambda / 2}}$

Similarly, for $\mathrm{HF}_{c, \text { odd }}^{0,1 ; e^{\lambda / 2}}$ and $\mathbb{T}^{\bullet}$-circuits of height 0 . We get:
$\mathrm{HF}_{c, \text { even }}^{0,1 ; \mathrm{e}^{\lambda / 2}}\left(\right.$ around every box, exists a $\mathbb{T}^{\circ}$-circuit of height 1 ) $=1$
$\mathrm{HF}_{c, \text { odd }}^{0,1 ; \mathrm{e}^{\lambda / 2}}\left(\right.$ around every box, exists a $\mathbb{T}^{\bullet}$-circuit of height 0$)=1$
Couple $f \sim \mathrm{HF}_{c, \text { even }}^{0,1 ; \mathrm{e}^{\lambda / 2}}$ and $g \sim \mathrm{HF}_{c, \text { odd }}^{0,1 ; \mathrm{e}^{\lambda / 2}}$ in the following way:

- outside of the outermost $\mathbb{T}^{\bullet}$-circuit of height 0 contained in a box $N \times N$ :

$$
g(i, j):=1-f(i-1, j)
$$

## Proof, step 3.2: $\mathrm{HF}_{c, \text { even }}^{0,1 ; \mathrm{e}^{\lambda / 2}} \succeq \mathrm{HF}_{c, 0 \mathrm{odd}}^{0,1 ; \mathrm{e}^{\lambda / 2}}$

Similarly, for $\mathrm{HF}_{c, \text { odd }}^{0,1 ; e^{\lambda / 2}}$ and $\mathbb{T}^{\bullet}$-circuits of height 0 . We get:
$\mathrm{HF}_{c, \text { even }}^{0,1 ; \mathrm{e}^{\lambda / 2}}$ (around every box, exists a $\mathbb{T}^{\circ}$-circuit of height 1 ) $=1$
$\mathrm{HF}_{c, \text { odd }}^{0,1 ; \mathrm{e}^{\lambda / 2}}\left(\right.$ around every box, exists a $\mathbb{T}^{\bullet}$-circuit of height 0$)=1$
Couple $f \sim \mathrm{HF}_{c, \text { even }}^{0,1 ; \mathrm{e}^{\lambda / 2}}$ and $g \sim \mathrm{HF}_{c, \text { odd }}^{0,1 ; \mathrm{e}^{\lambda / 2}}$ in the following way:

- outside of the outermost $\mathbb{T}^{\bullet}$-circuit of height 0 contained in a box $N \times N$ :

$$
g(i, j):=1-f(i-1, j)
$$

- inside of this circuit, $f$ and $g$ are independent.
