A skein theoretic model for the double affine Hecke algebras

H.R. Morton

University of Liverpool

BIRS January 2019
In the broad light of day mathematicians check their equations and their proofs, leaving no stone unturned in their search for rigour.

But, at night, under the full moon, they dream, they float among the stars and wonder at the mystery of the heavens: they are inspired.

Without dreams there is no art, no mathematics, no life.

*Michael Atiyah*
Peter Samuelson and I worked some years ago on the skein-based algebra of closed curves in the thickened torus.

Peter related this to a special case of the elliptic Hall algebra, following a paper of Schiffman and Vasserot, which connects the elliptic Hall algebra with quotients of the double affine Hecke algebras of Cherednik.
Peter Samuelson and I worked some years ago on the skein-based algebra of closed curves in the thickened torus.

Peter related this to a special case of the elliptic Hall algebra, following a paper of Schiffman and Vasserot, which connects the elliptic Hall algebra with quotients of the double affine Hecke algebras of Cherednik.

More recently Peter and I had a look at the models of the double affine Hecke algebras by Burella et al, and came up with a variant of these based this time on braids in the thickened torus.

We are hopeful that we can enhance these by including closed curves in the torus so as to get a skein based model for the complete elliptic Hall algebra which is consistent with our own earlier work and also the account of Schiffman and Vasserot.
Main sections

- Torus braids with a base string
- Double affine Hecke algebras
- The elliptic Hall algebra
Braids in the torus

Torus braids with a base string
Torus braids with a base string

We can use braids on $n$ strings in the thickened torus $T^2 \times I$, together with a single fixed base string $\{\ast\} \times I \subset T^2 \times I$ to construct an algebra.
Torus braids with a base string

We can use braids on $n$ strings in the thickened torus $T^2 \times I$, together with a single fixed base string $\{\ast\} \times I \subset T^2 \times I$ to construct an algebra.

Regard $T^2$ as given by identifying opposite pairs of sides in the unit square $[0, 1] \times [0, 1]$.

Take the base point $\ast$ to be the centre of the square. Fix $n$ endpoints for $n$-string braids in $T^2 \times I - \{\ast\} \times I$. 
Braids in the torus

This is a plan view from above.
Braids in the torus

A braid should be thought of as $n$ strings in $T^2 \times I$ which run monotonically upwards without meeting each other, along with a fixed base string.

We can imagine $n$ distinct points starting from our choice of endpoints and moving around the torus as time progresses, along with a base point $\ast$ which does not move.
A braid should be thought of as $n$ strings in $T^2 \times I$ which run monotonically upwards without meeting each other, along with a fixed base string.

We can imagine $n$ distinct points starting from our choice of endpoints and moving around the torus as time progresses, along with a base point $\ast$ which does not move.

In general we want to use a ribbon (a framed curve), rather than a string, but that can be done implicitly here in a consistent way.
Making an algebra

The based skein $H_n(T^2, \ast)$ is defined to be $\mathbb{Z}[s^{\pm 1}, c^{\pm 1}]$-linear combinations of braids, up to equivalence, subject to the local skein relation

$$
\begin{align*}
\begin{array}{c}
\uparrow & \downarrow \\
\downarrow & \uparrow \\
\end{array} \\
- \\
\begin{array}{c}
\uparrow & \downarrow \\
\downarrow & \uparrow \\
\end{array}
\end{align*}
= (s - s^{-1}) \\
\begin{array}{c}
\uparrow \\
\downarrow \\
\end{array}.
$$
Making an algebra

The based skein $H_n(T^2, \ast)$ is defined to be $\mathbb{Z}[s^\pm 1, c^\pm 1]$-linear combinations of braids, up to equivalence, subject to the local skein relation

$$\begin{align*}
\begin{array}{c}
\leftarrow \quad \rightarrow \\
\end{array} - 
\begin{array}{c}
\leftarrow \\
\end{array} &= (s - s^{-1}) \leftarrow \\
\end{align*}.$$

In addition a braid string is allowed to cross through the base string $\ast$ at the expense of multiplying by a parameter $c$ according to the local relation

$$\begin{align*}
\begin{array}{c}
\leftarrow \\
\end{array} \ast &= c^2 
\begin{array}{c}
\rightarrow \\
\end{array} \ast
\end{align*}.$$
Making an algebra

The based skein $H_n(T^2, \ast)$ is defined to be $\mathbb{Z}[s^{\pm 1}, c^{\pm 1}]$-linear combinations of braids, up to equivalence, subject to the local skein relation

\[ \begin{array}{c}
\begin{array}{c}
\includegraphics[width=1cm]{skein_relation_1}
\end{array}
- \begin{array}{c}
\includegraphics[width=1cm]{skein_relation_2}
\end{array}
= (s - s^{-1}) \begin{array}{c}
\includegraphics[width=1cm]{skein_relation_3}
\end{array}.
\end{array} \]

In addition a braid string is allowed to cross through the base string $\ast$ at the expense of multiplying by a parameter $c$ according to the local relation

\[ \begin{array}{c}
\begin{array}{c}
\includegraphics[width=1cm]{skein_relation_4}
\end{array}
= c^2 \begin{array}{c}
\includegraphics[width=1cm]{skein_relation_5}
\end{array}.
\end{array} \]

Composition of braids induces a product on $H_n(T^2, \ast)$, making it into an algebra over $\mathbb{Z}[s^{\pm 1}, c^{\pm 1}]$. 
Related algebras

The restriction to braids whose strings remain inside a cylinder $D^2 \times I \subset T^2 \times I - \{*\} \times I$ which contains the $n$ points but not the base point gives a sub-algebra.
Related algebras

The restriction to braids whose strings remain inside a cylinder $D^2 \times I \subset T^2 \times I - \{\ast\} \times I$ which contains the $n$ points but not the base point gives a sub-algebra generated by the elementary braids

$$\sigma_i = \begin{array}{c}
\begin{array}{c}
\uparrow \quad \uparrow \quad \uparrow \quad \uparrow \\
i \quad i+1
\end{array}
\end{array} \quad , \quad i = \ldots, n-1$$

The skein relation, applied at this crossing point, gives

$$\sigma_i - \sigma_i^{-1} = (s - s^{-1})\text{Id}$$
The restriction to braids whose strings remain inside a cylinder $D^2 \times I \subset T^2 \times I - \{\ast\} \times I$ which contains the $n$ points but not the base point gives a sub-algebra generated by the elementary braids

$$\sigma_i = \begin{array}{c c c c}
\uparrow & \uparrow & \uparrow & \uparrow \\
i & i + 1
\end{array}, \ i = \ldots, n - 1$$

The skein relation, applied at this crossing point, gives

$$\sigma_i - \sigma_i^{-1} = (s - s^{-1})\text{Id}$$

which becomes the quadratic relations

$$(\sigma_i - s)(\sigma_i + s^{-1}) = 0$$
They also satisfy Artin’s braid relations. These are

- Non-adjacent generators $\sigma_i, \sigma_j$ commute.
- $\sigma_i \sigma_{i+1} \sigma_i = \sigma_{i+1} \sigma_i \sigma_{i+1}$

The result is isomorphic to the Hecke algebra $H_n$ of type A.
They also satisfy Artin’s braid relations.

These are

- Non-adjacent generators $\sigma_i, \sigma_j$ commute.
- $\sigma_i \sigma_{i+1} \sigma_i = \sigma_{i+1} \sigma_i \sigma_{i+1}$

The result is isomorphic to the Hecke algebra $H_n$ of type A.

In some contexts the parameter $q$ or $t$ is used in place of $s^2$. 
Related algebras

The extensions to braids in either an annulus, or the whole torus, give models for the affine, or (we believe) double affine Hecke algebras, $\hat{H}_n, \breve{H}_n$. 
Pictorial views

We can indicate some simple braids by drawing the path of the moving points on a plan view.
We can indicate some simple braids by drawing the path of the moving points on a plan view.

For example, $\sigma_i$ appears in plan view as

```
          n
         / |
     i    \   |
       /     |
      /      |
     /       |
    /        |
   /         |
  /          |
 /           |
/    \       |
\    /       |
  \   /      |
    \ /     |
     \    |
      \   |
       \  |
        \|
```

$\sigma_i =$
Some key braids

Write $x_i$ for the braid in which point $i$ moves uniformly around the $(1, 0)$ curve in the torus,
Some key braids

Write $x_i$ for the braid in which point $i$ moves uniformly around the $(1,0)$ curve in the torus, and $y_i$ where point $i$ moves around the $(0,1)$ curve, with all other points remaining fixed.
Some key braids

Write $x_i$ for the braid in which point $i$ moves uniformly around the $(1, 0)$ curve in the torus, and $y_i$ where point $i$ moves around the $(0, 1)$ curve, with all other points remaining fixed.

In the plan view we have

\[ x_i = \text{[diagram]} \]
Some key braids

Write $x_i$ for the braid in which point $i$ moves uniformly around the $(1,0)$ curve in the torus, and $y_i$ where point $i$ moves around the $(0,1)$ curve, with all other points remaining fixed.

In the plan view we have

\[
x_i = \begin{array}{c}
\end{array}, \quad y_i = \begin{array}{c}
\end{array}
\]
View from the side

Seen from the side they look like

\[ x_i = \]

\begin{center}
\includegraphics[width=0.5\textwidth]{diagram}
\end{center}
View from the side

Seen from the side they look like

\[ x_i = \]

\[ y_i = \]
We can see that

\[
\sigma_i^{-1}x_i\sigma_i^{-1} = x_{i+1}
\]

\[
\sigma_i y_i \sigma_i = y_{i+1}.
\]
Visualising braid composition

In a plan view we assume that the paths we see are projections of braid strings which rise monotonically from their initial braid point to their final braid point.
Visualising braid composition

In a plan view we assume that the paths we see are projections of braid strings which rise monotonically from their initial braid point to their final braid point. The product of two braids corresponds to the concatenation of their paths.
In a plan view we assume that the paths we see are projections of braid strings which rise monotonically from their initial braid point to their final braid point. The product of two braids corresponds to the concatenation of their paths.

The braids \( \{x_i\} \) commute among themselves, since their paths in the plan view are disjoint.
Visualising braid composition

In a plan view we assume that the paths we see are projections of braid strings which rise monotonically from their initial braid point to their final braid point. The product of two braids corresponds to the concatenation of their paths.

The braids \{x_i\} commute among themselves, since their paths in the plan view are disjoint.

The same is true for the braids \{y_i\}, and equally the braids \sigma_i commute with \(x_j\) and \(y_j\) when \(j \neq i, i + 1\).
Visualising braid composition

We can use the plan view for a braid where two paths cross, taking the usual convention of knot crossings to show which strand lies at a higher level.
Visualising braid composition

We can use the plan view for a braid where two paths cross, taking the usual convention of knot crossings to show which strand lies at a higher level. For example in the plan view of $x_1y_2$ the path of point 1 lies below that of point 2, giving the views.
Visualising braid composition

We can use the plan view for a braid where two paths cross, taking the usual convention of knot crossings to show which strand lies at a higher level. For example in the plan view of $x_1y_2$ the path of point 1 lies below that of point 2, giving the views
Visualising braid composition

When two braids are composed there may be a path on the plan view that passes through a braid point at an intermediate stage.
Visualising braid composition

When two braids are composed there may be a path on the plan view that passes through a braid point at an intermediate stage. We can divert the path slightly away from the intermediate braid point.
Visualising braid composition

When two braids are composed there may be a path on the plan view that passes through a braid point at an intermediate stage. We can divert the path slightly away from the intermediate braid point.

For example the braid $x_1y_1$ starts with a plan view
Visualising braid composition

When two braids are composed there may be a path on the plan view that passes through a braid point at an intermediate stage. We can divert the path slightly away from the intermediate braid point.

For example the braid $x_1 y_1$ starts with a plan view
while $y_1 x_1$ diverts to

$$y_1 x_1 = \text{Diagram}$$
With further smoothing we get the plan view of the commutator

\[ x_1 y_1 x_1^{-1} y_1^{-1} = \]
Visualising braid composition

Moving this braid across the base string leads to

\[ x_1 y_1 x_1^{-1} y_1^{-1} = c^2 \]
Moving this braid across the base string leads to

\[ x_1 y_1 x_1^{-1} y_1^{-1} = c^2 \]

\[ := c^2 \beta_n \]
Visualising braid composition

Seen from the side

\[ \beta_n = \]

\[ \begin{array}{c}
1 \\
\uparrow \\
\downarrow \\
n \\
\uparrow \\
* \\
\end{array} \]
Visualising braid composition

We can alter the plan view near the projection of one of the braid points, where a path crossing nearby can be moved across the braid point like this
We can alter the plan view near the projection of one of the braid points, where a path crossing nearby can be moved across the braid point like this.
Braid relations

Apply this to the view of $y_1 x_2$ by moving the path from braid point 1 across braid point 2.
Braid relations

Apply this to the view of $y_1 x_2$ by moving the path from braid point 1 across braid point 2. This gives

$$y_1 x_2 =$$
Braid relations

Apply this to the view of $y_1x_2$ by moving the path from braid point 1 across braid point 2. This gives

$$y_1x_2 = \quad =$$
Apply this to the view of $y_1x_2$ by moving the path from braid point 1 across braid point 2. This gives

$$y_1x_2 = \quad = \quad = x_2\alpha_2$$
Braid relations

where

\[ \alpha_2 = \sigma_1^2 y_1, \]

and thus

\[ x_2 y_1^{-1} = y_1^{-1} x_2 \sigma_1^2. \]
A similar argument, moving one path across braid points $2 \ldots n$, shows that

$$y_1 x_2 x_3 \cdots x_n =$$
Further relations

A similar argument, moving one path across braid points 2\ldots n, shows that

\[ y_1 x_2 x_3 \cdots x_n = \]

\[ = \]

\[ = \]
Further relations

A similar argument, moving one path across braid points $2 \ldots n$, shows that

$$y_1x_2x_3 \cdots x_n = x_2x_3 \cdots x_n \alpha_n$$
Here

\[ \alpha_n = \ast = \beta_n y_1 \]
Here

\[ \alpha_n = \begin{array}{c}
\text{\textbullet} \\
\end{array} = \beta_n y_1 \]

Now

\[ \beta_n = c^{-2} x_1 y_1 x_1^{-1} y_1^{-1} \]

Hence

\[ y_1 x_2 x_3 \cdots x_n = c^{-2} x_2 x_3 \cdots x_n x_1 y_1 x_1^{-1}, \]
Here

\[ \alpha_n = y_1 x_2 x_3 \cdots x_n = c^{-2} x_1 y_1 x_1^{-1} y_1^{-1} \]

Now

\[ \beta_n = c^{-2} x_1 y_1 x_1^{-1} y_1^{-1} \]

Hence

\[ y_1 x_2 x_3 \cdots x_n = c^{-2} x_2 x_3 \cdots x_n x_1 y_1 x_1^{-1} \]

so that

\[ y_1 x_1 x_2 x_3 \cdots x_n = c^{-2} x_1 x_2 x_3 \cdots x_n y_1 \]
The case $n = 1$

When $n = 1$ there are only elements $x_1$ and $y_1$, and we have a model for the so-called ‘quantum torus’ with generators $x_1, y_1$ which $q$-commute,
The case $n = 1$

When $n = 1$ there are only elements $x_1$ and $y_1$, and we have a model for the so-called ‘quantum torus’ with generators $x_1, y_1$ which $q$-commute,

$$y_1x_1 = qx_1y_1$$

writing $q = c^{-2}$. 
The case $n = 1$

When $n = 1$ there are only elements $x_1$ and $y_1$, and we have a model for the so-called ‘quantum torus’ with generators $x_1, y_1$ which $q$-commute,

$$y_1 x_1 = q x_1 y_1$$

writing $q = c^{-2}$.

This is the simplest case $\hat{H}_1$ of a double affine Hecke algebra.
Double affine Hecke algebras
The **double affine Hecke algebra** $\mathcal{H}_n$ of Cherednik is an algebra over $\mathbb{Z}[s^{\pm 1}, q^{\pm 1}]$ generated by $\{T_i\}, 1 \leq i \leq n - 1, \{X_j\}, \{Y_j\}, 1 \leq j \leq n$
The **double affine Hecke algebra** $\mathcal{H}_n$ of Cherednik is an algebra over $\mathbb{Z}[s^\pm 1, q^\pm 1]$ generated by 

$$\{T_i\}, 1 \leq i \leq n - 1, \{X_j\}, \{Y_j\}, 1 \leq j \leq n$$

with relations

$$(T_i + s)(T_i - s^{-1}) = 0$$

$$T_i T_{i+1} T_i = T_{i+1} T_i T_{i+1}$$

$$[T_i, T_j] = 0, |i - j| > 1$$
The **double affine Hecke algebra** $\mathcal{H}_n$ of Cherednik is an algebra over $\mathbb{Z}[s^{\pm 1}, q^{\pm 1}]$ generated by

$$\{T_i\}, 1 \leq i \leq n - 1; \{X_j\}, \{Y_j\}, 1 \leq j \leq n$$

with relations

$$(T_i + s)(T_i - s^{-1}) = 0$$

$$T_i T_{i+1} T_i = T_{i+1} T_i T_{i+1}$$

$$[T_i, T_j] = 0, |i - j| > 1$$

$$X_{i+1} = T_i X_i T_i,$$

$$Y_{i+1} = T_i^{-1} Y_i T_i^{-1}$$
The *double affine Hecke algebra* $\mathcal{H}_n$ of Cherednik is an algebra over $\mathbb{Z}[s^{\pm 1}, q^{\pm 1}]$ generated by

$$\{T_i\}, 1 \leq i \leq n-1, \{X_j\}, \{Y_j\}, 1 \leq j \leq n$$

with relations

$$(T_i + s)(T_i - s^{-1}) = 0$$

$$T_iT_{i+1}T_i = T_{i+1}T_iT_{i+1}$$

$$[T_i, T_j] = 0, |i - j| > 1$$

$$X_{i+1} = T_iX_iT_i,$$

$$Y_{i+1} = T_i^{-1}Y_iT_i^{-1}$$

$$[T_i, X_j] = [T_i, Y_j] = 0, j \neq i, i + 1$$

$$[X_i, X_j] = [Y_i, Y_j] = 0$$
The double affine Hecke algebra $\mathcal{H}_n$ of Cherednik is an algebra over $\mathbb{Z}[s^{\pm 1}, q^{\pm 1}]$ generated by

$$\{ T_i \}, 1 \leq i \leq n - 1, \{ X_j \}, \{ Y_j \}, 1 \leq j \leq n$$

with relations

\begin{align*}
(T_i + s)(T_i - s^{-1}) &= 0 \\
T_i T_{i+1} T_i &= T_{i+1} T_i T_{i+1} \\
[T_i, T_j] &= 0, |i - j| > 1 \\
X_{i+1} &= T_i X_i T_i, \\
Y_{i+1} &= T_i^{-1} Y_i T_i^{-1} \\
[T_i, X_j] &= [T_i, Y_j] = 0, j \neq i, i + 1 \\
[X_i, X_j] &= [Y_i, Y_j] = 0 \\
X_1^{-1} Y_2 &= Y_2 X_1^{-1} T_1^{-2} \\
Y_1 X_1 \cdots X_n &= q X_1 \cdots X_n Y_1
\end{align*}
Comparison with the skein algebra

These equations are all satisfied in our skein algebra $H_n(T^2, \ast)$ taking $X_i = x_i$, $Y_i = y_i$, $T_i = \sigma_i^{-1}$ and $q = c^{-2}$. 
These equations are all satisfied in our skein algebra $H_n(T^2,\ast)$ taking $X_i = x_i$, $Y_i = y_i$, $T_i = \sigma_i^{-1}$ and $q = c^{-2}$.

We believe that this is an isomorphism of algebras.
Going further

There is scope for going further, and incorporating closed curves in the skein algebra. The reason for trying this is to model the elliptic Hall algebra, which is shown by Schiffman and Vasserot to relate to a limit of quotients of the algebras $\check{H}_n$. 
There is scope for going further, and incorporating closed curves in the skein algebra. The reason for trying this is to model the \textit{elliptic Hall algebra}, which is shown by Schiffman and Vasserot to relate to a limit of quotients of the algebras $\hat{H}_n$.

Key elements in their model are the power sums

\[ X_1^m + \cdots + X_n^m, \ Y_1^m + \cdots + Y_n^m \]

and commutators of them.
An important connection comes from the skein of the annulus with $n$ boundary points.
Skein theory appearance of power sums

An important connection comes from the skein of the annulus with \( n \) boundary points. Write \( Z_i \) for the element

\[
Z_i = \begin{array}{c}
\text{Diagram of skein}
\end{array}
\]
Skein theory appearance of power sums

An important connection comes from the skein of the annulus with $n$ boundary points. Write $Z_i$ for the element

$$Z_i = \begin{array}{c}
\text{Diagram 1} \\
\text{Diagram 2}
\end{array}$$

It is readily established that

$$- \begin{array}{c}
\text{Diagram 1} \\
\text{Diagram 2}
\end{array}$$
Skein theory appearance of power sums

An important connection comes from the skein of the annulus with \( n \) boundary points.
Write \( Z_i \) for the element

\[
Z_i = \begin{array}{c}
\text{annulus with } n \text{ boundary points}
\end{array}
\]

It is readily established that

\[
(s - s^{-1}) \sum Z_i
\]
For each $m$ there is also a well-established element $P_m$ in the skein of the annulus which satisfies the relation

\[ P_m - P_m = (s^m - s^{-m}) \sum Z_i^m \]
Realising power sums in the torus

Placing the annulus in the direction of the $(1, 0)$ curve in the torus, and including the closed curve decorated by $P_m$ leads to

\[ P_m - P_m \]
Realising power sums in the torus

Placing the annulus in the direction of the \((1, 0)\) curve in the torus, and including the closed curve decorated by \(P_m\) leads to

\[
P_m - P_m = (s^m - s^{-m}) \sum_i X_i^m
\]

This is the view from above.
Realising power sums in the torus

By moving the closed curve in the second diagram round the torus past the base string we can then write

\[ (s^m - s^{-m}) \sum_i X_i^m = (1 - c^{2m}) \]

where \( P_m \) represents the curve on the torus.
Similarly

\[(s^m - s^{-m}) \sum_i Y_i^m = (1 - c^{2m})\]
The elliptic Hall algebra
The elliptic Hall algebra has generators $u_x$ for every $x \in \mathbb{Z}^2$, satisfying certain commutation relations.
The elliptic Hall algebra has generators $u_x$ for every $x \in \mathbb{Z}^2$, satisfying certain commutation relations.

Schiffman and Vasserot’s comparison with the double affine Hecke algebras $\check{H}_n$ requires the prescription of an image for each $u_x$, and a check on their commutation properties.
The elliptic Hall algebra

The elliptic Hall algebra has generators $u_x$ for every $x \in \mathbb{Z}^2$, satisfying certain commutation relations.

Schiffman and Vasserot’s comparison with the double affine Hecke algebras $\hat{H}_n$ requires the prescription of an image for each $u_x$, and a check on their commutation properties.

Our aim is to see whether we can construct elements in our skein setting which might correspond to the elements $u_x$. 
The elliptic Hall algebra has generators $u_x$ for every $x \in \mathbb{Z}^2$, satisfying certain commutation relations.

Schiffman and Vasserot’s comparison with the double affine Hecke algebras $\mathcal{H}_n$ requires the prescription of an image for each $u_x$, and a check on their commutation properties.

Our aim is to see whether we can construct elements in our skein setting which might correspond to the elements $u_x$.

We could then use the skein algebras $\mathcal{H}_n(T^2, \ast)$, enhanced with suitable closed curves, as models for the full elliptic Hall algebra.
Here is a speculative, and maybe overoptimistic approach.

All the same it does give a nice interpretation in the DAHA setting, which is independent of \( n \) to a large extent, provided that our skein construction really gives us isomorphisms with \( \hat{H}_n \).
Fix a disc $D$ in $T^2$ which includes the braid points and the base point. A suitable choice for our purposes is a neighbourhood of the diagonal in the square.
Any oriented embedded curve in the complement of this disc is determined up to isotopy by a primitive element $y \in \mathbb{Z}^2$, representing the homology class of the curve.
Any oriented embedded curve in the complement of this disc is determined up to isotopy by a primitive element $y \in \mathbb{Z}^2$, representing the homology class of the curve.

For each primitive $y$ define an element $W_y$ of the skein $H_n(T^2, *)$ by the oriented curve corresponding to $y$, along with vertical braid strings and base string.

The closed curve is taken to be framed by its neighbourhood in $T^2$. 
Construction of elements $\mathcal{W}_x$

For any other non-zero $x \in \mathbb{Z}^2$ write $x = my$ with $m > 0$ and $y$ primitive, and define $\mathcal{W}_x$ to be $\mathcal{W}_y$ with the closed curve decorated by the element $P_m$.

Write $d(x) = m$ to denote the multiple $m$. 
We then have plan views of $W_{(\pm m,0)}$ and $W_{(0,\pm m)}$ as

\[ W_{(m,0)} = \begin{array}{ccc}
\bullet & \star \\
\uparrow & & \downarrow \\
& P_m
\end{array} \quad , \quad W_{(-m,0)} = \begin{array}{ccc}
\bullet & \star \\
& & \downarrow \\
& P_m
\end{array}, \]

\[ W_{(0,m)} = \begin{array}{ccc}
\bullet & \star \\
\uparrow & & \downarrow \\
& P_m
\end{array} \quad , \quad W_{(0,-m)} = \begin{array}{ccc}
\bullet & \star \\
& & \uparrow \\
& P_m
\end{array}. \]
Relating power sums to the elements $W_x$

Our equations above show that

\[
(1 - c^{2m}) W_{(m,0)} = (s^m - s^{-m}) \sum x_i^m, \\
(c^{-2m} - 1) W_{(-m,0)} = (s^m - s^{-m}) \sum x_i^{-m} \\
(c^{-2m} - 1) W_{(0,m)} = (s^m - s^{-m}) \sum y_i^m \\
(1 - c^{2m}) W_{(0,-m)} = (s^m - s^{-m}) \sum y_i^{-m}.
\]
Our best hope for a compatible skein version of $u_x$ is to take

$$u_x = \frac{1}{s^m - s^{-m}} W_x$$

with $m = d(x) > 0$. 
For non-zero $x \in \mathbb{Z}^2$ Schiffman and Vasserot define elements $P_x$ in the spherical algebra $\mathcal{S}\mathcal{H}_n$.

Here $\mathcal{S}\mathcal{H}_n$ is defined as $e\mathcal{H}_ne$, where $e \in \mathcal{H}_n$ is the symmetrizer idempotent in the finite Hecke algebra $\mathcal{H}_n$. 
For non-zero $x \in \mathbb{Z}^2$ Schiffman and Vasserot define elements $P_x$ in the \textit{spherical algebra} $S\mathcal{H}_n$.

Here $S\mathcal{H}_n$ is defined as $e\mathcal{H}_n e$, where $e \in H_n$ is the \textit{symmetrizer} idempotent in the finite Hecke algebra $H_n$.

In their comparisons with the elliptic Hall algebra they make the assignment

$$u_x \rightarrow \frac{1}{q^m - 1} P_x$$

with $m = d(x)$.

A skein theoretic model for the double affine Hecke algebras
Comparison

Using the identification of $H_n(T^2, \ast)$ with $\mathcal{H}_n$, where $q = c^{-2}, s^2 = t$, we can compare our elements $W_x$ to $P_x \in S\mathcal{H}_n$. 

H.R. Morton  
A skein theoretic model for the double affine Hecke algebras
Using the identification of $H_n(T^2, \ast)$ with $\tilde{H}_n$, where $q = c^{-2}, s^2 = t$, we can compare our elements $W_x$ to $P_x \in S\tilde{H}_n$.

The symmetrizer idempotent $e$ has a well-established representation as a linear combination of $n$-braids in the disc $D^2$. 
Using the identification of $H_n(T^2, \ast)$ with $\check{H}_n$, where $q = c^{-2}, s^2 = t$, we can compare our elements $W_x$ to $P_x \in S\check{H}_n$.

The symmetrizer idempotent $e$ has a well-established representation as a linear combination of $n$-braids in the disc $D^2$.

**Theorem**

For every non-zero $x \in \mathbb{Z}^2$ we have

$$(q^m - 1)eW_x e = (s^m - s^{-m})P_x,$$

where $m = d(x) > 0$. 

H.R.Morton  
A skein theoretic model for the double affine Hecke algebras
Our calculations above establish this when $x = (\pm m, 0), (0, \pm m)$. 
Our calculations above establish this when \( x = (\pm m, 0), (0, \pm m) \).

The general definition of \( P_x \) uses automorphisms of \( \bar{H}_n \) induced by Dehn twists on the torus starting from \( P_{0,m} \), and these same automorphisms also carry \( W_{0,m} \) to \( W_x \).
Hopes and fears

Peter Samuelson and I are encouraged in this approach by our earlier result in Duke Mathematical Journal.

We show there that the elliptic Hall algebra with $q = 1$ is isomorphic to the skein algebra $H(T^2)$ of closed curves in $T^2$, with no base point, and no braid points.
Hopes and fears

Our earlier work gives a nice commutativity relation for the elements $W_x$ when there are no braid points or base point.

**Theorem (Samuelson and Morton)**

$$[W_x, W_y] = (s^d - s^{-d})W_{x+y}$$

where $d = \det[x \ y]$. 
Our earlier work gives a nice commutativity relation for the elements $W_x$ when there are no braid points or base point.

**Theorem** (Samuelson and Morton)

$$[W_x, W_y] = (s^d - s^{-d})W_{x+y}$$

where $d = \det[x \ y]$.

This relation between $W_x$ and $W_y$ also works in our model for $\mathcal{H}_n$ when $x = (1, 0)$ and $y = (0, m)$.

This corresponds to the commutator relation between $u_x$ and $u_y$ in the elliptic Hall algebra in this case.
It would be nice to work directly with elements such as $W_x$ in $\dot{H}_n$ without passing to the spherical versions.

It seems though that some involvement of the spherical algebra is needed to cover the full relations from the Hall algebra.
Hopes and fears

It would be nice to work directly with elements such as $W_x$ in $\hat{H}_n$ without passing to the spherical versions.

It seems though that some involvement of the spherical algebra is needed to cover the full relations from the Hall algebra.

In the case $x = (-1, 0)$ and $y = (1, m)$ the commutator relation in the elliptic Hall algebra is a bit more complicated, and we have not been able to get a direct proof of the corresponding relation in our skein version of $S\hat{H}_n$. 
The future

We will continue to dream.
